

Lookmefy Android Build Difference Report

Previous: 0.1.6 / versionCode 13

New: 0.1.7 / versionCode 14

Prepared for Android Play Store testing and APK handoff

Date: 29 August 2026

Scope Note

This document explains the difference between the previous Android build and the new Android build, the problems connected to the testing error, and why the version was increased. It intentionally does not include repair commands, file-edit instructions, or step-by-step solution details.

Final Artifact Identity

AAB	mobile/release/lookmefy-0.1.7-vc14-release.aab
APK	mobile/release/lookmefy-0.1.7-vc14-release.apk
Package	com.lookmefy.app
Release intent	Patch-level Android testing release for Play Store review and partner testing.

Executive Summary

The previous Android testing build showed the catalog error because the installed mobile binary was not aligned with the live production API domain used by Lookmefy. The backend service was running, but an already-built mobile app keeps the API target that was bundled into it at build time. Server deployment alone cannot rewrite a submitted or installed AAB/APK.

The new Android release is version 0.1.7 with Android versionCode 14. It preserves the same Android application identity, but it gives Play Store and external testers a fresh binary that can replace the previous 0.1.6 / versionCode 13 build.

Main Point

The catalog problem was not simply a backend restart issue. The app binary under review needed to be replaced because the old submitted file continued carrying old build-time production configuration.

Short Answer

- Previous Android version: 0.1.6 with versionCode 13.
- New Android version: 0.1.7 with versionCode 14.
- The new version number is needed because Google Play requires every replacement Android upload to have a higher versionCode than the previous upload.
- The user-visible issue was the All Products catalog card showing "Something needs attention" because product data could not be reached from the installed build.
- The already submitted AAB/APK remains old until a new build is uploaded or sent to the relevant testing team.
- This document avoids implementation steps by request.

Version And Artifact Comparison

Area	Previous build	New build	Why it matters
App version	0.1.6	0.1.7	Human-readable patch version increased so reviewers and testers can distinguish the corrected build from the old one.
Android versionCode	13	14	Play Store update ordering depends on versionCode. A new upload must be higher than the previous accepted or submitted build.
Android package ID	com.lookmefy.app	com.lookmefy.app	The package identity stays the same, so Android treats it as an update to the same app rather than a different app.
Display name	Lookmefy	Lookmefy	No intentional branding change in this Android patch build.
Production API domain	Old review build was associated with api.lookmefy.com or non-current production target risk.	New build contains https://api.lookmefy.in/api .	Lookmefy web and API domain are under .in. The mobile client must contact the same live API family.
Catalog behavior	All Products could fail with "Something needs attention".	Expected to request catalog data from the live .in API.	The visible error affects browsing, product discovery, and flows that depend on product records.
Submitted file status	Already submitted or installed file cannot be modified in place.	Fresh AAB/APK files generated for replacement testing.	Reviewers only test the binary they receive. A repository or server update does not mutate old binaries.
Play Store artifact	Previous AAB with versionCode 13.	New AAB with versionCode 14.	The AAB is the correct artifact type for Play Store testing tracks.
Manual test artifact	Older APK, if shared, may still show old behavior.	New APK with versionCode 14.	APK is useful for direct install or partner testing when they request APK instead of AAB.
Signing identity	Expected FitLook upload signing lineage.	Verified FitLook signing identity.	Signing continuity matters for Android updates and Play Console acceptance.

Problems Connected To The Error

1. API Domain Mismatch

The mobile app displayed the catalog error on the Home screen under All Products. This happens when the app cannot get usable product catalog data from the backend. The previous testing binary was associated with the wrong production API domain path, specifically the .com API target instead of the live .in API target used by Lookmefy.

The confusing part is that the backend could still be healthy while the mobile app failed. That is possible because the app and the server are separate release units. A working backend does not guarantee that an old mobile binary is pointing to it.

2. Already Submitted Mobile Files Are Immutable

Once an AAB or APK is built, uploaded, or sent to a testing team, the configuration inside that file is frozen. Later code pushes, backend restarts, DNS changes, or local edits do not automatically change what is inside that already distributed binary.

This is why testers can continue seeing the old error even after the backend deployment looks successful. They may still be running the earlier binary.

3. Google Play Version Ordering

Google Play does not decide Android updates only from the visible app version. It uses the numeric versionCode. If the previous submitted build used versionCode 13, a replacement build must use a higher number. VersionCode 14 is the next valid update value.

The visible version was increased from 0.1.6 to 0.1.7 so the release also looks different to humans, testers, and review teams. This is a patch-level version change, not necessarily a feature release.

4. Local, Native, And Review Configuration Ambiguity

React Native and Expo Android apps can have more than one place where version and environment information appears. The app configuration, native Android Gradle configuration, local environment file, and cloud build profile can all influence builds depending on the build path.

The risk is that one build path may look correct while another still produces an old version or old API target. This matters when trying to create files for Play Store review quickly.

5. AAB And APK Purpose Confusion

AAB and APK are not interchangeable for every audience. Play Store testing tracks expect an AAB in most modern Android release flows. An APK is useful for direct installation or external partner review when that team specifically requests an installable APK.

Why The Version Was Changed

- VersionCode changed from 13 to 14 because Android and Google Play require a strictly higher versionCode for replacement uploads.

- App version changed from 0.1.6 to 0.1.7 so humans can recognize this as a new patch build and not confuse it with the already submitted package.
- The version change helps Play Store testers, internal testers, and partner teams confirm they are testing the newer build.
- The change also gives a cleaner release trail: old testing build equals 0.1.6 / 13, new testing build equals 0.1.7 / 14.
- The new version does not mean a large product feature release. It is best understood as a production-readiness patch build for Android testing.

Important

If the same versionCode were reused, Play Store would treat the upload as invalid or not newer. This is the practical reason the Android versionCode had to move forward.

Expected Difference In Behavior

Previous 0.1.6 / versionCode 13

- Static or bundled Home screen content could still appear, such as banners and categories.
- The product catalog request could fail, causing the All Products area to show the attention/error card.
- Any flow that depends on live product records could become unreliable, including product discovery, wishlist actions, recommendations, outfit generation, or checkout-linked browsing.
- Backend deployment status alone would not change this installed app behavior if the binary kept the old API target.

New 0.1.7 / versionCode 14

- The Android package identity remains the same, so this is still the Lookmefy Android app.
- The build is expected to contact the live production API at <https://api.lookmefy.in/api>.
- The catalog should load when DNS, HTTPS, network access, and backend routes are healthy.
- Existing testers must actually receive or install the new build before this behavior is visible on their devices.

Production Impact And Safety Notes

- No Android package rename is intended. Keeping com.lookmefy.app avoids creating a separate app identity.
- No database migration is implied by this mobile build difference report.
- No Play Store listing content change is implied by the Android version bump itself.
- No iOS App Store build is produced by an Android AAB/APK build. iOS has a separate build number and review pipeline.
- If an existing iOS binary was also built with an old API target, iOS would need its own fresh build and submission path.
- The new Android files were generated as release artifacts and are separate from backend deployment.
- Users or reviewers who still have the old version installed may continue seeing the old error until the installed app is updated or replaced.

- Any future outage in DNS, HTTPS certificate, backend health, product routes, or network access can still cause a catalog error even with the newer app build.

Verification Evidence

The new Android release artifacts were checked after generation. This section records observable validation results only; it does not include build commands or repair instructions.

APK metadata	Package com.lookmefy.app, versionCode 14, versionName 0.1.7.
APK signing	Verified with Android signature scheme v2. Signing certificate subject: CN=FitLook, OU=Mobile, O=FitLook, L=Mumbai, ST=Maharashtra, C=IN.
AAB signing	AAB jar verification passed and showed FitLook signing identity.
Bundled API	Both generated Android artifacts contain https://api.lookmefy.in/api in the bundled JavaScript assets.
Old API strings	The generated Android JavaScript bundle did not show api.lookmefy.com or the raw load balancer API URL.
Artifact sizes	AAB approximately 56 MB. APK approximately 76 MB.

Checksums

AAB SHA-256	e9092712bcb117b088f6617a302bfc38973e960e8dd6f01deac0609ad17c2f35
APK SHA-256	f0d4aa6b2fc082536813af3d2d071e9d619c07db16a4ffc2ec9c6f8e479a511b

What This Report Does Not Contain

- No terminal commands.
- No step-by-step fix instructions.
- No secret values, keystore passwords, or private deployment credentials.
- No backend implementation details beyond the high-level reason the mobile build needed replacement.
- No guarantee that Play Store or PhonePe will complete review instantly; external review timelines are outside the app binary itself.

Final Conclusion

The previous Android build and the new Android build differ mainly in release identity and production API alignment. The new build is version 0.1.7 with versionCode 14, which is necessary for Play Store replacement testing after a versionCode 13 build. The catalog error came from the mobile app failing to reach the correct live catalog service from the submitted or installed binary, not from the Home screen design itself.

For testing and review identity, the key label is: Lookmefy Android 0.1.7, versionCode 14, package com.lookmefy.app.
